

Disaster Recovery Design Pattern - S3 Cross-Region Replication (CRR)

Why a Nigerian Company Would Use CRR to af-south-1

A Nigerian company may use Amazon S3 Cross-Region Replication (CRR) to replicate data from us-east-1 to af-south-1 (Cape Town) for several reasons:

- Lower latency for users and applications in Africa
- Better disaster recovery and business continuity
- Improved data durability and availability
- Data sovereignty and regional compliance considerations
- Faster access for East and Southern African users

Disaster Recovery Scenario

If the primary AWS region (us-east-1) experiences an outage or failure, the replicated copy stored in af-south-1 remains safe and accessible.

This ensures:

- Continued access to critical business data
- Reduced downtime
- Faster recovery during regional outages
- Higher resilience for production workloads

AWS Services Used

- Amazon S3
- S3 Cross-Region Replication (CRR)
- IAM Roles & Policies
- Versioning

Real-World Use Case

A hospital, fintech company, or media platform in Nigeria could replicate customer data and backups to af-south-1 to improve reliability and maintain operations during outages in another AWS region.
